

1 Downhole Tool

2

3 The present invention relates to downhole tools for use  
4 in the oil and gas industry and in particular, though not  
5 exclusively, to a tool including blades to condition, by  
6 grooming, the inside walls of casing or liner used in a  
7 well bore.

8

9 In a cased or lined well bore it is necessary to remove  
10 debris and other particulate matter from the inner wall  
11 of the casing or liner before performing certain  
12 operations in the well bore such as setting a packer or  
13 running a completion. Such conditioning of the well bore  
14 is generally provided by brushing or scraping the inner  
15 wall of the casing or liner. The aim being to provide a  
16 smooth clean surface upon which a seal can reliably be  
17 made.

18

19 It is known in the art to provide brushes on the outer  
20 surface of a cylindrical body mounted in a work string,  
21 to 'brush' debris from the inner wall of casing or liner  
22 as the string is run or removed from the borehole. Such  
23 brushes have limited application downhole as, due to the

1 'wet' environment in which they must work, they are prone  
2 to clogging.

3

4 Scrapers have also been arranged on a cylindrical body  
5 mounted in a work string. These are generally spiral  
6 metal blades which scrape against the inner wall of the  
7 casing or liner. They must be perfectly sized to match  
8 the casing or liner in use and can damage the surface of  
9 the liner or casing if grit becomes trapped between the  
10 outer edge of the blade and the inner wall of the casing  
11 or liner.

12

13 To overcome these disadvantages, scrapers made of rubber  
14 materials have been developed which reform within the  
15 casing to cover any mismatch in size and provide a  
16 'wiper' to the casing or liner wall. Unfortunately,  
17 rubber has a limited life span as it wears quickly in  
18 downhole environments.

19

20 It is an object of at least one embodiment of the present  
21 invention to provide a downhole tool for conditioning a  
22 casing or liner wall which obviates or mitigates the  
23 disadvantages of the prior art.

24

25 It is a yet further object of at least one embodiment of  
26 the present invention to provide a downhole tool which  
27 can be used when the work string is rotated, run in or  
28 pulled out of the well bore.

29

30 It is a yet further object of at least one embodiment of  
31 the present invention to provide a method of forming a  
32 scraper for a downhole tool.

33

1 According to a first aspect of the present invention  
2 there is provided a downhole tool for conditioning a  
3 casing or liner wall, the tool comprising a substantially  
4 cylindrical body connectable in a work string, a sleeve  
5 located around the body, one or more blades located on  
6 the sleeve, wherein each blade has a circular peripheral  
7 edge distal to the sleeve and each blade is manufactured  
8 from a composite material which comprises a polymeric  
9 fibre.

10

11 Preferably the polymeric fibre is chosen from the group  
12 comprising polyaramid fibres, polyethylene fibres,  
13 polypropylene fibres, polyacryl fibres, polyester fibres,  
14 polyacryl fibres or poly{2,6-diimidazo[4,5-b4',5'-  
15 e]pyridinylene-1,4(2,5-dihydroxy)phenylene} (PIPD)  
16 fibres.

17

18 Preferably the polyaramid fibres are produced from poly-  
19 paraphenylene terephthalamide commonly referred to by its  
20 trade name Kevlar® or Twaron®.

21

22 Preferably the polyethylene fibres are those commonly  
23 referred to as Dyneema® or Spectra®.

24

25 Preferably the polyester fibres are those commonly  
26 referred to as Diolen®.

27

28 Preferably the poly{2,6-diimidazo[4,5-b4',5'-  
29 e]pyridinylene-1,4(2,5-dihydroxy)phenylene} (PIPD) fibres  
30 are commonly referred to as M5®.

31

32 Composites including polymeric fibres provide a blade  
33 which both has a degree of flexibility and sufficient

1 abrasion resistance to successfully 'knock-off' debris  
2 from the casing or liner wall and cope with small  
3 mismatches between the blade diameter and the inner wall  
4 diameter. This allows the blades to be sized to the  
5 actual casing ID (Inner Diameter).

6  
7 By providing a complete uninterrupted circular peripheral  
8 edge to the blade, maximum strength across the blade is  
9 achieved while additionally the blade can provide a  
10 cleaning action without the need to rotate the blade  
11 within the well bore.

12  
13 Preferably the composite comprises KEVLAR®. Preferably  
14 also the composite further includes carbon. Preferably  
15 also the composite includes glass fibre. Thus in the  
16 preferred embodiment the blades are made from a KEVLAR®  
17 carbon glass composite.

18  
19 Preferably the sleeve is adapted to rotate independently  
20 of the body. Thus the body can rotate with the work  
21 string while the sleeve may remain static. This may be  
22 referred to as a 'through rotational mandrel'.

23  
24 Preferably the sleeve includes a plurality of bypass  
25 ports to allow fluid to pass between the sleeve and the  
26 tool. More preferably there are pairs of bypass ports,  
27 each bypass port of each pair being arranged on either  
28 side of the one or more blades to provide an entry bypass  
29 port and an exit bypass port respectively. This  
30 arrangement provides a bypass around the blade(s).

31  
32 Preferably one or more channels are located on an outer  
33 surface of the body. More preferably the channel(s) align

5

1 with the ports so bypassing fluid can travel through the  
2 channel(s). This provides a flow through area to the tool  
3 in use.

4

5 Alternatively one or more ports may be located through  
6 the one or more blades, the ports being distal from the  
7 peripheral edge of the blade(s). Thus a fluid bypass is  
8 provided through the blades without interfering with the  
9 360 degree grooming action on the wall of the  
10 casing/liner.

11

12 Preferably the sleeve includes one or more jetting ports.  
13 Preferably the jetting ports include nozzles.

14 Advantageously the jetting ports are arranged adjacent  
15 the blades so that fluid bypassing the blades jets from  
16 jetting ports to provide a cleaning action on the blades.

17

18 Preferably the blades are located between flexible  
19 members. This allows additional substantially  
20 longitudinal movement of the blades and provides spacers  
21 for use between the blades. This arrangement provides  
22 blades which are not radially biased. The blades may  
23 further be mounted on a cartridge which is located on the  
24 body. This arrangement allows easy interchange of the  
25 blade configuration without the need to handle individual  
26 blades. Additionally the cartridge may be radially  
27 biased.

28

29 Advantageously the blades may be arranged in sets of  
30 groups on the sleeve. By providing groups of blades  
31 together the blades support each other to give a strength  
32 equivalent to use of a thicker blade, while maintaining  
33 the flexibility achieved by each narrow blade.

1 Preferably the blades have an inner circumferential edge  
2 such that they form a torus, sometimes referred to as  
3 'do-nut' shaped. Preferably also a diameter of the blade  
4 at the inner circumferential edge is greater than an  
5 outer diameter of the body at the location of the blade  
6 on the body. This mismatch may provide a clearance so  
7 that the blade may move radially with respect to the  
8 body. The blades may therefore 'retract' towards the  
9 tool, away from the low side of the casing/liner, if the  
10 tool is used in horizontal or deviated casing. This can  
11 protect the blades, so they don't bear the weight of the  
12 tool, if a stabiliser or centraliser, preferably sized to  
13 drift, is present. Advantageously, the blade may be  
14 radially biased by a spring or the like against the body.

15

16 Preferably the tool includes one or more additional  
17 sleeves. Advantageously these additional sleeves are  
18 centralisers as are known in the art to assist in keeping  
19 the tool centrally aligned in the casing or liner. Thus  
20 the additional sleeves may comprise a plurality of raised  
21 portions on an outer surface thereof. Preferably the  
22 raised portions are arranged equidistantly around the  
23 outer surface of the additional sleeve(s).

24

25 Advantageously the sleeve(s) are held to the tool body by  
26 one or more holding devices to prevent longitudinal  
27 movement of the sleeve(s) on the tool body. Preferably  
28 each sleeve abuts another sleeve or a stop on the tool  
29 body. An opposite end of a sleeve may then be held in  
30 place by the holding device. Preferably the holding  
31 device comprises a split ring, a retaining ring and a  
32 circlip.

33

1 Preferably the holding device is located around the body  
2 and abuts the sleeve. The split ring preferably rests  
3 against an end of the sleeve and comprises two  
4 semicircular members. The split ring bears the load of  
5 the sleeve. Preferably the retaining ring comprises a  
6 circular member including a circular groove located at a  
7 first end thereof. More preferably the split ring  
8 locates in the groove such that the split ring is  
9 retained by the retaining ring. Preferably the circlip is  
10 located at a second end of the retaining ring. The  
11 circlip holds the retaining ring in place and bears no  
12 load from the sleeve. By taking the load of the sleeve on  
13 the split ring, this load is transferred to the body.

14

15 Preferably the tool may include an additional operating  
16 portion. The additional operating portion may allow the  
17 tool to provide an additional function in the casing or  
18 liner. Preferably the additional operating portion is a  
19 packer as is known in the art, the packer being arranged  
20 above the sleeve on the body. The tool is then a packer  
21 including a sacrificial scraper mounted ahead of the  
22 packer.

23

24 Alternatively the additional operating portion may be a  
25 cementing unit as is known in the art, the unit being  
26 arranged above the sleeve on the body. Thus the tool is a  
27 wiper plug wherein the blades provide a barrier between  
28 the cement slurry below and the displacing fluid above.

29

30 According to a second aspect of the present invention  
31 there is provided a holding device for preventing  
32 longitudinal movement of a sleeve(s) on a substantially

1 cylindrical tool body, the device comprising a split  
2 ring, a retaining ring and a circlip.

3

4 The holding device advantageously transfers the load of  
5 the sleeve on to the tool body. The holding device may be  
6 located around the body and abuts the sleeve.

7

8 Preferably the split ring preferably comprises two  
9 semicircular members. The split ring may rest against an  
10 end of the sleeve and bears the load of the sleeve.

11

12 Preferably the retaining ring comprises a circular member  
13 including a circular groove located at a first end  
14 thereof. More preferably the split ring locates in the  
15 groove such that the split ring is retained by the  
16 retaining ring.

17

18 Preferably the circlip is located at a second end of the  
19 retaining ring. The circlip holds the retaining ring in  
20 place and bears no load from the sleeve. By taking the  
21 load of the sleeve on the split ring, this load is  
22 transferred to the body.

23

24 According to a third aspect of the present invention  
25 there is provided a method of conditioning a casing or  
26 liner in a well bore, the method comprising the steps:

27

- 28 (a) locating on a work string, a blade having a  
29 circular peripheral edge and made from a  
30 composite material which comprises a polymeric  
31 fibre;  
32 (b) inserting the work string into the well bore to  
33 a position where the peripheral edge makes

1 contact with an inner wall of the casing or  
2 liner; and

3 (c) moving the work string relative to the inner  
4 wall to thereby move the blade relative to the  
5 wall and provide a grooming action on the wall.

6  
7 Step (c) may be by rotation of the work string, by  
8 running in the well or by pulling out of the well. In a  
9 preferred method the blade may move independently of the  
10 work string.

11  
12 Step (b) may include making 360 degree contact between  
13 the peripheral edge and the inner wall.

14  
15 Preferably the method may include the step of providing a  
16 fluid bypass to allow fluid to bypass the peripheral  
17 edge.

18  
19 According to a fourth aspect of the present invention  
20 there is provided a method of forming a scraper for a  
21 downhole tool, the method comprising the steps;

22  
23 (a) providing a sheet of composite material  
24 comprising a polymeric fibre;  
25 (b) instantaneously subjecting the material to  
26 first water pressure from a water jet; and  
27 (c) moving the material relative to the jet to cut  
28 a profile of a scraper from the material while  
29 maintaining the water at substantially the  
30 first pressure.

31  
32 Composite materials typically have laminated structures.  
33 Preferably the material is a glass fibre/carbon/polymeric

10

1 fibre structure. The polymeric fibre may be as described  
2 for the first aspect.

3

4 By applying the pressure instantaneously to the material,  
5 as opposed to the traditional method of gradually  
6 increasing the pressure, we have found that the water  
7 does not spread between the layers a break up the  
8 structure.

9

10 Preferably an abrasive such as garnet is mixed with the  
11 water. Preferably the water pressure is around 50,000psi  
12 for a 10mm thick sheet, from a jet of 0.8mm diameter and  
13 a cutting rate of 1m/min.

14

15 Embodiments of the present invention will now be  
16 described, by way of example only, with reference to the  
17 following drawings of which:

18

19 Figures 1(a) and (b) are illustrative views of a body (a)  
20 and tool(b) of a downhole tool according to an embodiment  
21 of the present invention;

22

23 Figures 2(a) and (b) are cross-sectional views through  
24 the tool of Figure 1;

25

26 Figures 3(a) - (h) are cross-sectional views through a  
27 downhole tool according to a further embodiment of the  
28 present invention;

29

30 Figure 4 is a cross-sectional view through a portion of  
31 the tool of Figure 3;

32

11

1 Figures 5(a) and (b) are schematic diagrams of a holding  
2 device according to an embodiment of the present  
3 invention; and

4  
5 Figure 6 is a schematic view of a tool, according to an  
6 embodiment of the present invention, operating in a well  
7 bore.

8  
9 Reference is initially made to Figure 1(b) of the  
10 drawings which illustrates a downhole tool, generally  
11 indicated by reference numeral 10, according to an  
12 embodiment of the present invention. Tool 10 primarily  
13 comprises a substantially cylindrical body 12, best seen  
14 in Figure 1(a), and a sleeve 14 on which is located six  
15 blades 16a-f.

16  
17 The body 12 is of single piece hollow bore construction  
18 and includes a threaded section 18 at a first end 20 of  
19 the tool 10 and a box section 22 at a second end 24 of  
20 the tool 10. The threaded section 18 and box section 22  
21 are as typically used to connect the tool to a mandrel in  
22 a work string (not shown). The body 12 includes an outer  
23 surface 26 on which is located a ledge 28 formed  
24 circumferentially around the body 12. Ledge 28 provides a  
25 stop on the body 12. At a central location 30 four  
26 channels 32, of rectangular shape are arranged  
27 longitudinally on the surface 26. Further on the surface  
28 30 are arranged two further circumferencial grooves 34,36  
29 for holding split rings (not shown) and a circlip 38.

30  
31 In order, on the body 12, are arranged from the ledge 28,  
32 a number of components, each separated by bearing rings  
33 40a-d so that the components are through rotational.

12

1 The first component is a centraliser 42a which is a  
2 sleeve including longitudinally arranged raised portions  
3 44. Four raised portions 44 are arranged equidistantly  
4 around the centraliser 42a to evenly space the tool 10  
5 from the wall of a casing or liner in which the tool 10  
6 is inserted.

7  
8 A middle component is the sleeve 14 on which is located a  
9 blade cartridge 46. The blade cartridge 46 holds the six  
10 equally spaced blades 16a-f. Each blade is a torus of  
11 KEVLAR®/carbon/glass fibre composite, with an outer  
12 diameter greater than the diameter at the raised portions  
13 44 of the centralisers 42. The material provides a  
14 flexibility so that the blades 16a-f can fit within close  
15 sized casing or liner, while being strong enough to  
16 scrape and remove debris as the edge 48, contacts the  
17 casing or liner wall.

18  
19 Though KEVLAR® is the preferred choice of polymeric  
20 fibre, it will be appreciated that other fibres such as  
21 polyaramid fibres including poly-paraphenylene  
22 terephthalamide commonly referred to by its trade name  
23 Twaron®; polyethylene fibres including those commonly  
24 referred to as Dyneema® or Spectra®, polypropylene  
25 fibres, polyacryl fibres, polyester fibres including  
26 those commonly referred to as Diolen®; polyacryl fibres;  
27 or poly{2,6-diimidazo[4,5-b4',5'-e]pyridinylene-1,4(2,5-  
28 dihydroxy)phenylene} (PIPD) fibres commonly referred to  
29 as M5®.

30  
31 The blades 16 are preferably formed from sheets of the  
32 composite material. Due to the layered structure of the  
33 material traditional methods of gradually applying water

13

1 pressure from a jet to cut out the blade tend to cause  
2 the structure to split and explode. This is caused by  
3 the water penetrating between the layers. In the present  
4 invention, a high water pressure is applied  
5 instantaneously to the structure. This has been found to  
6 prevent splitting in the structure. A typical pressure  
7 would be 50,000psi on up to 10mm thick structure from a  
8 0.8mm diameter jet. 80 mesh garnet is added to the water  
9 as an abrasive to assist in cutting. In this way a one  
10 piece blade can be cut with the preferred circumferential  
11 outer edge which is uniform with no interruptions i.e a  
12 circle. A further circle can be cut from the middle of  
13 the blade through which the body can be inserted.

14

15 The blades 16a-f are spaced by rubber rings 50 which  
16 provide a degree of flexibility to the movement of the  
17 blades 16a-f. It will be appreciated however that the  
18 blades need not be equally spaced nor the rings be of  
19 rubber, any material providing a degree of flexibility  
20 would be appropriate.

21

22 Through the rings 50 are arranged ports which include  
23 nozzles 54 to jet fluid from behind the cartridge 46 onto  
24 the blades 16a-f to provide a cleaning action and remove  
25 any debris or particles which have become stuck to the  
26 surface of the blades 16a-f. Further the sleeve 14 is  
27 made in three parts 56a,b,c. The parts are screwed  
28 together to form circularly arranged ports 58a,b through  
29 which fluid can pass from the casing or liner to the  
30 channels 32 in the body 12. Ports 58a,b are large slots  
31 to provide an unobstructed flow path through the tool 10  
32 when the blades 16a-f are sealingly engaged to the wall  
33 of the casing or liner. Thus removal of debris will

14

1 continue successfully even if debris builds up behind or  
2 in front of a blade because it is the circumference of  
3 the blade that knocks off the debris which is independent  
4 of any debris build up. The arrangement of this bypass  
5 will be described hereinafter with reference to Figures  
6 2.

7

8 The third and final component is a second centraliser  
9 42b, identical to the first centraliser 42a. The  
10 centralisers 42a,b stabilise the tool 10 within the  
11 casing or liner to drift.

12

13 All the components are held between the ledge 28 and  
14 split rings (not shown). The split rings are held within  
15 a retaining ring 60 which in turn is held by the circlip  
16 38. All the components are through rotational so that  
17 they can remain static while the body 12 and the mandrel  
18 to which it is attached can rotate in the well bore. The  
19 split ring/retainer ring 60 and circlip 38 arrangement is  
20 described hereinafter with reference to Figures 5.

21

22 Reference is now made to Figures 2 of the drawings which  
23 shows the central portion 30 of the tool 10 of Figure  
24 1(b). Like parts have been given the same reference  
25 numeral to maintain clarity. Ports 56 locate over the  
26 channels 32 to provide a fluid bypass under the blades  
27 16a-f. The fluid bypass is bi-directional and thus can  
28 redirect fluid when the tool 10 is run in, pulled out or  
29 if fluid is circulated or reverse circulated in the  
30 casing or liner.

31

32 Also shown in Figures 2 are the arrangement of the blades  
33 16a-f with respect to the body 12 of the tool 10. As

15

1 described previously, blades 16a-f are a torus or 'do-  
2 nut' shape having an outer peripheral edge 48 and an  
3 inner circumferential edge 62. The diameter at the edge  
4 62 is greater than the diameter at the surface 64 of the  
5 cartridge 46. In this way the blades 16a-f can float on  
6 the sleeve 14 by being able to move perpendicularly to  
7 the longitudinal axis of the tool 10. At all times,  
8 however, a portion of the blade 16 remains within the  
9 ring 50. The blades 16a-f float independently of each  
10 other. If the tool 10 is used in a deviated or horizontal  
11 well bore, there will be a tendency for the tool 10 to  
12 rest on the low side of the casing or liner. The blades  
13 16 would therefore have to bear the weight of the tool 10  
14 and the work string. In order to prevent this the blades  
15 or the blade cartridge float to remain concentric to the  
16 casing or liner and allow the centralisers 42a,b to  
17 support the weight of the tool 10.

18

19 Reference is now made to Figure 3 and 4 of the drawings  
20 which illustrates a downhole tool, generally indicated by  
21 reference numeral 110, according to a further embodiment  
22 of the present invention. Like parts to those of the  
23 embodiment described in Figures 1 and 2, have been given  
24 the same reference numeral with the addition of 100. Tool  
25 110 has the same components as tool 10 but they are  
26 arranged differently on the body 112.

27

28 Body 112 has two ledges 66a,b located on the outer  
29 surface 126. Against one ledge 66b is located a  
30 centraliser 142b which is held in place by split rings 64  
31 and a retaining ring 160b. The split ring 64b is of two  
32 part construction as is known in the art. The retaining  
33 ring 160b can either screw on to the body 112 or can in

16

1    tun be held in place by a circlip (not shown). From the  
2    second ledge is arranged the sleeve 114 with a second  
3    centraliser 142a abutted thereto. The second centraliser  
4    142a is held in place by an identical split ring 64a and  
5    retaining ring 160a arrangement as the first centraliser  
6    142b.

7

8    Sleeve 114a is made up of three parts 156a,b,c. This is  
9    best seen with the aid of Figure 4. Central section 156b  
10   also carries the cartridge 146 on which the blades 116  
11   are mounted. In this embodiment the blades 116 are  
12   mounted in two sets of three. By tightly stacking the  
13   blades 116 against the rubber rings 150, each set  
14   provides a strength equal to a single blade having triple  
15   the thickness but still has the flexibility afforded to  
16   the thinner blades 116. And pieces 156a,c include  
17   rectangular ports 158 to provide for fluid flow into the  
18   channels 132. The portions 156 of the sleeve 114 are  
19   further held in place by an additional split ring 64c  
20   located between the central 156b and outer 156a parts.

21

22   Reference is now made to Figures 5 of the drawings which  
23   illustrates a holding device, generally indicated by  
24   reference numeral 68, according to a further embodiment  
25   of the present invention. Holding device 68 is as used in  
26   the tool 10 and like parts to those in Figures 1 and 2  
27   have been given the same reference numeral with the  
28   addition of 200. The device comprises a split ring 264, a  
29   retaining ring 260 and a circlip 238.

30

31   On the tool body 212 are arranged two circumferential  
32   grooves 234,236. Facing the sleeve (not shown) is  
33   arranged the split ring 264 in the first groove 234. The

17

1 split ring is made of two semi-circular portions which  
2 compress against the body 112 when an inner surface 70 of  
3 the retainer ring 260 is pushed against them. The  
4 retainer ring 260 is held against the split ring 264 by  
5 the circlip 238 which itself locates in the second groove  
6 236. It is the split ring 264 which bears the load of a  
7 sleeve abutting the holding device 68. This load is  
8 transferred to the body 212 through the split rings 264.  
9 Thus no load appears on the circlip 238, it merely keeps  
10 the retaining ring 260 in place.

11

12 In use, a blade 16,116, is chosen which is equal to or  
13 slightly greater than the diameter of the casing or liner  
14 which requires to be groomed. The blades 16,116 are  
15 arranged on the blade cartridge 46,146 and mounted on the  
16 sleeve 14,114. The sleeve 14,114 and the centralisers  
17 42,142 are located on the body 12,112 and held in place  
18 by the holding device 68 if used. The body 12,112 is then  
19 connected to the mandrel of a work string using the box  
20 22,122 section and threaded 18,118 section at each end  
21 24,20 of the tool 10,110. The work string is run in the  
22 well bore until the blades reach the location of the  
23 casing or liner to be groomed. The work string is then  
24 moved relative to the casing or liner and as the edges 48  
25 contact the wall of the casing or liner, debris and  
26 particles will be 'knocked-off'. Additionally through the  
27 sealing engagement of the blades 16,116 to the wall, the  
28 surface of the wall will be effectively wiped clean.  
29 During this process fluid within the casing or liner will  
30 pass freely through the tool 10,110 by entering the ports  
31 58a,158a, passing through the channels 32,132 and exiting  
32 through the ports 58b,158b. It will be appreciated that

18

1 fluid can flow in the opposite direction through the  
2 ports 58,158 also.

3

4 Reference is now made to Figure 6 of the drawings which  
5 illustrates a downhole tool, generally indicated by  
6 reference numeral 80, including the tool 10,110 of the  
7 present invention. Tool 80 has a first operating section  
8 82 which contains the known components for performing a  
9 function within casing or liner 84. Those skilled in the  
10 art will appreciate that section 82 may be a packer,  
11 cementing tool or the like which all require to contact  
12 the inner surface 86 of the casing or liner 84. The  
13 second operating section 88, mounted ahead of the first  
14 operating section 82, on the work string 90, is the tool  
15 10,110 as described previously herein. In use, tool 80  
16 provides a grooming function to condition the surface 86  
17 ahead of operation of the section 82.

18

19 The principal advantage of the present invention is that  
20 it provides a downhole tool for conditioning, by  
21 grooming, the inner wall of a casing or liner which  
22 utilises a composite material which comprises a polymeric  
23 fibre. This composite provides a flexibility and strength  
24 over the prior art blade materials of metal and rubber.

25

26 A further advantage of the present invention is that it  
27 provides a downhole tool wherein the individual blades  
28 provide 360 degree coverage so that the tool can be used  
29 when run in or pulled out of a well bore. Further fluid  
30 bypass is provided to maintain fluid circulation in the  
31 well bore.

32

19

1 A yet further advantage of the present invention is in  
2 the provision of a method for cutting the composite  
3 material to form a blade.

4

5 It will be appreciated by those skilled in the art that  
6 various modifications may be made to the invention  
7 hereindescribed without departing from the scope thereof.  
8 For example, any number of sleeve including the blades  
9 may be mounted on a body. Additionally, the blades could  
10 be fixed to the sleeve i.e. not floating, but be non-  
11 concentric with the work string, either individually or  
12 together. It will also be appreciated that while the  
13 blades in the Figures are shown as individual circular  
14 discs, a strip of composite arranged in a spiral around  
15 the sleeve could also be used, thereby reducing the need  
16 for the separate by pass.
